

Write a Java application that will read words from a file and display the words, one per line, in a JFrame. The JFrame should use a grid layout of one row and two columns. In the left column the words should be listed in their original order from the file. In the right column the words should be listed in alphabetical (sorted) order.

There can be several words on one line of the file, each separated by a comma (use a *StringTokenizer* to separate the words).

Modify the SelectionSort code so that it can sort an array of Strings. To compare two strings use the method *compareTo* in class String.
